Hepatoprotective Effect of Feeding Celery Leaves Mixed with Chicory Leaves and Barley Grains to Hypercholesterolemic Rats

Nehal M. Belal
Department of Nutrition and Food Science, Faculty of Home Economics, Helwan University, Egypt

ABSTRACT
Celery, Chicory leaves and Barley grains are valuable in weight loss diets and regulate lipid metabolism. They may reduce risk of fatty liver. The present study aimed to investigate the effect of diet supplementation with celery, chicory and barley powder on liver enzymes and blood lipids in rats fed cholesterol enriched diet. In this study used four groups of rats fed 3% cholesterol were supplemented diet to induce hypercholesterolemia and one group was fed on cholesterol free basal diet. The dry powder of celery leaves, chicory leaves and barley grains was separately added to the basal diet at 10% concentration or in combination of three plants at 15% for four weeks. Biochemical analyses of serum liver enzymes and blood lipids as well as histopathological examination of liver were performed. Feeding of diet supplemented lowered the elevated serum level of liver enzymes and blood lipids in rats. While, feeding plant combination of celery, chicory and barley at 15% concentration (5% from each) was more effective in decreased the elevating of liver enzymes (AST, ALT and ALP), lowered blood lipids. The histopathological lesions seen in the livers of hypercholesterolemic rats were ameliorated by feeding this plant mixture. This study recommends that dietary intake of plant mixture concentration can be beneficial to patients suffering from hypercholesterolemia and liver diseases.

Key words: Celery, chicory, barley, biochemical analysis, hypercholesterolemia

INTRODUCTION
Celery (Apium graveolens, Family Apiaceae) is an excellent source of Vitamin C. It is a very good source of dietary fiber, potassium, folate, manganese and Vitamin B6. Celery is also a good source of calcium, Vitamin B1, Vitamin B2, magnesium, Vitamin A, phosphorus and iron. (Mitra et al., 2001) Celery, Apium graveolens L, is a plant from the family of Apiaceae that has been used as food and as medicine. A review of the literature indicates that celery has been cultivated for the last 3,000 years (Momin and Nair, 2001). Apium graveolens has been used in traditional medicine primarily as a diuretic and to treat bronchitis, asthma, liver and spleen diseases (Singh and Handa, 1995). Also, it is known that celery in combination with other plants can help lower blood pressure (Chevallier, 1998). A. graveolens has been extensively studied for its biological activities. Aqueous extract of celery caused significant reduction in serum total cholesterol level in hypercholesterolemic rats (Tsi and Tan, 2000). Recently, dietary fiber have been paid more and more attention due to the physiological functions (Geng et al., 2005) Also, medicinal plants are increasingly being used as herbs in most part of the world today (Abolaji et al., 2007).

Chicory (Chicorium intybus, Family Asteraceae) leaves is a vegetable whose green leafy part is often used in cooking. Previous studies on chicory extracts and/or formulations containing the roots or leaves revealed that they produce hepatoprotective (Ahmed et al., 2008;
Krylova et al., 2006) and antioxidant effects. (Sarawathy and Devi, 2001; Rossetto et al., 2005). Antioxidants are compounds that dispose, scavenge and suppress the formation of free radicals, or oppose their actions (Iribhogbe et al., 2011). Recently, Urias-Silvas et al. (2007) concluded that inulin (fructans) extracted from chicory regulate appetite and lipid/glucose metabolism. It has also promising effects on the body weight and fat mass development. In particular, increases in the amount of fat in diet have been known to be associated with the risk of obesity and hyperlipidemia in human and rodents by altering cholesterol and triglyceride levels in plasma and tissues (Abdel-Rahman et al., 2009). Hyperlipidemia is known to enhance the risk of coronary heart disease, fatty liver disease and carcinogenesis which is associated with reactive oxygen species formation (Roberts et al., 2006). In recent years, many studies have focused on the bioavailability of phenolic compounds in the prevention and treatment of obesity. Phenolic compounds and flavonoids have pharmacological properties such as antioxidant, antimutagenic, anti-thrombogenic, anti-inflammatory, anticancer and anti-hyperlipidemic. They are widely distributed in plants and form part of the human diet (Son and Lewis, 2002).

Previous studies on chicory extracts and formulations containing its roots or leaves revealed that they produce hepatoprotective (Mitra et al., 2001; Ahmed et al., 2003; Krylova et al., 2006); antihyperglycemic (Petlevski et al., 2003) and antioxidant effects (Sarawathy and Devi, 2001; Rossetto et al., 2005). Furthermore, Urias-Silvas et al. (2007) concluded that inulin-type fructans extracted from chicory regulate appetite and lipid/glucose metabolism. It has also promising effects on the body weight and fat mass development.

Barley (Hordeum vulgare L, Family Poaceae) is an annual cereal grain which serves as a major animal feed crop. Barley makes a natural choice for healthful benefits as it is rich in protein, carbohydrates, dietary fibers, chromium, fat and it is cholesterol free (Mahmoud, 2002).

Moreover, Jenkins et al. (2003) concluded that barley may be used as a part of vegetarian diet, because it decreases total lipids and reduces the risk of developing liver disease as fatty liver (Jenkins et al., 2003).

The present study is initiated in an effort to clarify the variation in the amount of fiber from celery, chicory and barley sources on serum liver enzymes and blood lipid profile in hypercholesterolemic rats.

MATERIALS AND METHODS

Materials

Plants: In 2009, Celery leaves and Chicory leaves were obtained from a local market of Herbs and Medicinal plants, Cairo Egypt. Barley grains (Giza 128 variety) was obtained from Agricultural Research Center, Giza, Egypt. The selected plant materials were air-dried, grinded in an electrical blender into a fine powder which was packed in air-tight plastic bags till use for basal diet supplementation.

The chemical composition of plants used is shown in Table 1.

Cholesterol: It was purchased from El-Gomhuryia Company for Chemical Industries, Cairo.

Rats: Adult male albino rats of Sprague Dawley strain weighing 150-160 g body weight were used in this study.

Methods

Preparation of basal diet: Basal diet was prepared according to Reeves et al. (1993).

Determination of the nutritional value in the Agricultural Research Center, Giza, Egypt. Percent daily values are based on a 2000 calorie diet.

**Induction of hypercholesterolemia:** It was induced by feeding rats on basal diet supplemented with 3% cholesterol for four weeks before start of the experiment. After feeding period, a random blood sample was withdrawn from the orbital sinus of the eye and serum total cholesterol was measured to insure that hypercholesterolemia was induced (Shinnick et al., 1990).

**Experiments and grouping of rats:** Forty two male albino rats were used in this experiment. Rats were divided into 6 equal groups of 7 animals each. Group (1) was fed on the basal diet as a negative control group while the other groups were fed on 2% cholesterol supplemented diet for four weeks for induction of hypercholesterolemia. Group (2) was left as a positive control (hypercholesterolemic), while groups (3, 4, 5) and (6) were fed on experimental diets containing 10% celery, 10% chicory, 10% barley and 15% mixture (5% from each) of celery (5% celery = 22.7 g edible weight), chicory (5% chicory = 18.5 g edible weight) and barley respectively for four weeks. During the feeding period body weight gains and food efficiency ratios were calculated according to Chapman et al. (1959).

At the end of experimental period, the rats were anaesthetized by ether and blood samples were collected. Blood samples were centrifuged for 20 min at 3000 rpm to separate the serum which was kept at-10°C till biochemical analysis of liver enzymes, total cholesterol, triglycerides and lipoprotein fractions. Livers of the sacrificed rats were removed and preserved in 10% neutral formalin solution till histopathological examination.

**Biochemical analyses:** The collected serum samples were used for estimation of aspartate and alanine aminotransferases (AST and ALT) enzymes according to the method described by
Bergmeyer et al. (1978) and alkaline phosphatase (ALP) according to the method described by King (1965).

Serum total cholesterol and triglycerides were calorimetrically determined (Allain et al., 1974; Wahlefeld, 1974).

High density lipoprotein cholesterol (HDL-C) was calorimetrically determined, very low density lipoprotein cholesterol (VLDL-C) and low density lipoprotein cholesterol (LDL-C) was mathematically calculated (Richmond, 1973).

**Histopathological examination:** Livers of the scarified rats were dissected, removed and fixed in 10% formalin solution. The fixed specimens were then trimmed, washed and dehydrated in ascending grades of alcohol. These specimens were cleared in xylene, embedded in paraffin, sectioned at 4-6 microns thickness and stained with Hematoxylen and Eosin (H and E) then examined microscopically (Carleton, 1980).

**Statistical analysis:** Results are expressed as mean values with their standard deviation of the mean (Snedecor and Cochran, 1986).

**RESULTS**

As shown in Table 2, feeding normal rats on basal diet supplemented with cholesterol for four weeks significantly increased Body Weight Gain (BWG%) and Food Efficiency Ratio (FER). Feeding hypercholesterolemic rats on diet supplemented with 10% celery significantly decreased BWG% and FER while diets supplemented with 10% chicory or 10% barley or 15% mixture of the three plants caused significant increases in BWG% and FER.

It is clear from Table 3 that feeding of diet supplemented with celery, chicory and barley plant powder, alone and combined, for four weeks to hypercholesterolemic rats significantly decreased the levels of AST, ALT and ALP enzymes in the serum, compared to the control positive group.

**Table 2:** Effect of diet supplementation with celery, chicory or barley and their combination on food intake (FI), body weight gain (BWG %) and food efficiency ratio (FER) in hypercholesterolemic rats (n = 7)

As demonstrated in Table 4, feeding experimental diets supplemented with celery, chicory and barley plant powder, alone and combined, for four weeks to hypercholesterolemic rats significantly decreased levels of total cholesterol and triglycerides in the serum, as compared to the control positive group. Feeding hypercholesterolemic rats on diets supplemented with celery, chicory and barley plant powder, caused a significant decrease in serum level of LDLc and VLDLc but significantly increased the levels of HDLc. As it is well known that LDLc is bad cholesterol so these plant material when added to basal diet improved lipid profile.

Histopathological examination: The biochemical observations reported in this study were supplemented by histopathological examination of liver sections of hypercholesterolemic rats. The obtained results showed that examination of livers of the normal (negative control ve) rats fed on the basal diet had normal histological picture of hepatic lobule that consists of central vein surrounded by normal hepatocytes Fig. 1. Examination of liver of hypercholesterolemic rats showed severe fatty degeneration of the hepatocytes and infiltration of leucocytes in hepatic sinusoid (Fig. 2). Livers of hypercholesterolemic rats fed on diet containing celery 10% showed little vacuolar degeneration of hepatocytes and mild fatty degeneration of hepatocytes as shown in Fig. 3. Examination of livers of hypercholesterolemic rats fed on diet supplemented with chicory 10% showed only mild fatty degeneration of the hepatocytes as illustrated in Fig. 4. Hypercholesterolemic rats fed on experimental diet containing barley 10% showed little vacuolar degeneration of hepatocytes and mild leucocytic infiltration around central vein (Fig. 5).

Fig. 6: Liver of rats fed on basal diet containing 15% mixture of the three plant materials showing almost normal histology of hepatic lobule (H and E X 100)

Examination of livers obtained from hypercholesterolemic rats fed on diet supplemented with a mixture of celery, chicory and barley at 15% revealed almost normal hepatic lobules as illustrated in Fig. 6.

DISCUSSION

The finding results of Table 2 was similar to that reported by Urias-Silvas et al. (2007) who concluded that inulin (fructans) extracted from chicory regulate appetite and has a promising effect on the body weight.

From Table 3 finding that effect of dietary fiber supplementation was similar to that reported by Tsi and Tan (2000) for celery extracts and by increasing bile acid secretion (Ahmed et al., 2003; Shimaa, 2008).

For chicory leaves and barley grains. The previous studies reported that different extracts of celery leaves or chicory leaves or barley grains effectively lower the elevated serum levels of AST, ALT and ALP enzymes (Yang et al., 2003).

From Table 4 finding that, the cholesterol lowering effect of celery reported in this study was similar to that previously reported by Tsi and Tan (2000). Moreover; the same concluded that the mechanism underlying the hypocholesterolemic activity of celery extracts (aqueous and butanol) could be possibly due to presence of sugar or amino acid side chains (s) compounds. Also, celery contains Vitamin C which is a known immune system booster and reduces the free radicals in the body. Also reduce the risk of asthma, osteoarthritis and rheumatoid arthritis. To top it off, the Vitamin is also thought to increase heart health.

The results of the present study about the effective of celery agreed with Kamal et al. (2009) who demonstrated that the lipid lowering action of this natural product may be mediated through inhibition of hepatic cholesterol biosynthesis, increased fecal bile acids excretion and enhanced plasma lecithin: Cholesterol acyltransferase activity and reduction of lipid absorption in the intestine.

The potassium and sodium in celery juice helps to regulate body fluid and stimulate urine production, making it an important help to rid the body of excess fluid (Nilsson, 2009).

Ni and Dom (2009) is suggested that the rich presence of tanins in chicory can keep the level of LDL (harmful) cholesterol in check. This can keep our heart healthy.

In addition, the chicory has been used in the folk medicine of Pakistan for treating liver disease and hepatic system related disorders. A group of clinical researchers recently isolated a phenolic compound called esculetin, from the extracts of the chicory and they further confirmed that is a
hepatoprotectant compound. The compound showed liver protecting activity in mice with hepatic damage induced by paracetamol and carbon tetrachloride. This extract inhibited the oxidative degradation of DNA in tissue debris of mice liver. In addition, high content of soluble fiber, inulin, chicory can reduce strain on liver by removing extra water and toxin (Kim and Shin, 1998). Inulin is soluble in water and not hydrolyzed by human digestive enzymes, it is expected to behave like a soluble fiber and to have a hypolipidemic effect. This might treat jaundice, hepatitis, hepatic congestion, etc. Also by stimulating the flow of bile, chicory is considered to treat gallstones, biliary insufficiency, gastritis and splenomegaly (Ahmed et al., 2003; Krylova et al., 2006). Insulin lowers serum cholesterol when added to the diet of rats, may decrease cholesterol synthesis by inhibiting hydroxymethylglutaryl-CoA reductase. A mechanism of action of oligofructose was associated with the modulation of de novo cholesterol synthesis by short chain fatty acids produced by the gut microflora during the fermentation process (Brosnahan and Mony, 2009). Concerning barley, barley may be used as a part of the vegetarian diet because it decreases serum total lipids. Moreover, whole-grain barley is lower in fat, protein and calories, and higher in total dietary fiber that increasing whole-grain consumption can reduce the risk of coronary heart disease and can help with weight maintenance (Jenkins et al., 2003). The results of the present work about the effective of barley agreed with Ahmad et al. (2009) who demonstrated that barley have a concentration of soluble fibers called β-glucan. These effects are associated with increased excretion of bile acids and neutral sterols, increased catabolism of cholesterol and reduced absorption of cholesterol and fat (Talati et al., 2009; Kamaljit et al., 2011).

This finding is in agreement, to some extent, for celery and for chicory in rats. Chicory is purported to have several health benefits, The short-chain fatty acids produced through the fermentation of soluble fiber in the large intestine serve to stabilize blood glucose levels, lower Low-Density Lipoproteins (LDL) or “bad” cholesterol in the blood, increase the production of immune cells, the concentrated barley beta-glucan in hypercholesterolemic men and women (Behall et al., 2004; Keenan et al., 2007).

Histopathological examination of liver sections of hypercholesterolemic rats was nearly similar histopathological findings were obtained in CCI4-hepatotoxic rats when given orally chicory extracts. No available literatures on the effects of celery and barley on the histology of liver could be obtained (Popovic et al., 2006).

In conclusion, dietary intake of plant mixture of celery, chicory and barley at 15% for four weeks may be beneficial for patients suffering from hypercholesterolemia and liver disease as it lowers the elevated serum liver enzymes, total cholesterol and triglycerides, improves lipid profile in cholesterol fed rats.

RECOMMENDATIONS

Diet supplementation with this plant mixture produces an excellent effect on the histology of liver as it ameliorates the hepatic damage seen in the liver of hypercholesterolemia.

ACKNOWLEDGMENT

My grateful appreciation is extended to Dr. M. A. Shalaby for his reviewing this work.
